

Patent Application

TREATMENT OF BENIGN PROSTATIC HYPERPLASIA

CROSS-REFERENCE TO RELATED APPLICATIONS

- 5 [0001] This application claims benefit of U.S. provisional application nos. 60/496,163 (filed 18 August 2003), 60/488,265 (filed July 18, 2003); 60/472,907 (filed 22 May 2003), 60/460,012 (filed 2 April 2003), 60/458,846 (filed 28 March 2003), 60/458,665 (filed 28 March 2003), 60/458,663 (filed 28 March 2003), 60/442,344 (filed 23 January 2003), and 60/441,110 (filed 17 January 2003), each of which is
10 incorporated herein by reference in its entirety for all purposes.

FIELD OF THE INVENTION

- [0002] The invention relates to treatment and prevention of benign prostatic hyperplasia, and has application in the field of medicine and related fields, including
15 chemistry, medicinal chemistry, and molecular biology.

BACKGROUND OF THE INVENTION

- [0003] Benign Prostatic Hyperplasia (BPH), a disease in which prostate epithelial cells grow abnormally and block urine flow, afflicts more than 10 million adult males in the United States, and many millions more throughout the rest of the world. Until
20 relatively recently, surgical intervention was the only treatment of the disease, and even today, surgery is the treatment of last resort, almost inevitably relied upon when other treatments are not, or cease to be, effective. Prostate surgery and recovery therefrom is painful, and the surgery itself may not be effective and poses the risk of serious side effects. For a recent review, see Barry, 2001 (full citations are provided below).
25 [0004] Only two classes of drugs are currently available to treat the symptoms of BPH. One class includes compounds that inhibit production of the active form of

- testosterone (dihydrotestosterone or DHT). Use of drugs in this class can cause a loss of libido and loss of muscle mass and tone in males and is associated with an increased occurrence of high grade prostate cancer. In addition, this therapy is limited by the very long delay (months) between first administering the drug and significant reduction in
- 5 prostate size in the patient. The second class of currently used drugs for BPH, alpha adrenergic blockers, acts by relaxing the smooth muscles, allowing urine to pass through the urethra more freely. While this class of drugs reduces symptoms more rapidly than the first, it does not reduce the size of the prostate or prevent it from growing larger, which can lead to eventual surgical intervention.
- 10 [0005] Thus, there is a significant, unmet need for drugs that can treat the underlying disease condition of BPH without serious side effects. The present invention meets that need.

SUMMARY OF THE INVENTION

- 15 [0006] The invention provides methods and compositions for treating BPH in a human subject by administration of Ionidamine or a Ionidamine analog to the subject. Pharmaceutical compositions useful for treatment of BPH, including sustained release formulations, are also provided. In one embodiment, the formulation is orally administered and permits once-a-day dosing of a therapeutically effective dose of the
- 20 compound.

BRIEF DESCRIPTION OF THE FIGURES

- [0007] Figure 1 shows structures for Ionidamine (I, R = Cl), tolnidamine (I, R = CH₃), AF-2364 (II) and AF-2785 (III).
- 25 [0008] Figure 2 shows the expression of HIF-1 α in LNCaP cells under normoxic and hypoxic conditions and in the presence and absence of Ionidamine. Figure 2A shows an assay using a nuclear extract. Figures 2B and 2C show an assay using a whole cell extract.
- [0009] Figure 3 shows the expression of HIF-1 α in PC-3 cells under normoxic
- 30 and hypoxic conditions and in the presence and absence of Ionidamine. Figures 3A

and 3C show an assay using a nuclear extract. Figure 3B shows an assay using a whole cell extract.

[0010] Figure 4 shows Ionidamine-induced apoptosis in LNCaP (Figure 4A) and PC-3 (Figure 4B) cells.

5 [0011] Figure 5 shows Ionidamine-induced apoptosis in prostate epithelial cells.

[0012] Figure 6 shows Ionidamine-induced apoptosis in prostate epithelial cells (Figure 6A) and prostate stromal cells (Figure 6B).

[0013] Figure 7 shows the effect of 0 – 600 µM Ionidamine on expression of HIF-1 α and other proteins as determined in whole cell extracts from LNCaP cells cultured 10 under hypoxic conditions.

[0014] Figure 8 shows the effect of 0 – 600 µM Ionidamine on expression of HIF-1 α and other proteins as determined in nuclear extracts from LNCaP cells cultured under hypoxic conditions.

15 DETAILED DESCRIPTION OF THE INVENTION

1. Definitions

[0015] The following definitions are provided to assist the reader. Unless otherwise defined, all terms of art, notations and other scientific or medical terms or terminology used herein are intended to have the meanings commonly understood by 20 those of skill in the chemical and medical arts. In some cases, terms with commonly understood meanings are defined herein for clarity and/or for ready reference, and the inclusion of such definitions herein should not necessarily be construed to represent a substantial difference over the definition of the term as generally understood in the art.

[0016] As used herein, "treating" a condition or patient refers to taking steps to 25 obtain beneficial or desired results, including clinical results. For purposes of this invention, beneficial or desired clinical results include, but are not limited to, alleviation or amelioration of one or more symptoms of BPH, diminishment of extent of disease, delay or slowing of disease progression, amelioration, palliation or stabilization of the disease state, and other beneficial results described below.

- [0017] As used herein, “reduction” of a symptom or symptoms (and grammatical equivalents of this phrase) means decreasing of the severity or frequency of the symptom(s), or elimination of the symptom(s).
- [0018] As used herein, “administering” or “administration of” a drug to a subject (and grammatical equivalents of this phrase) includes both *direct administration*, including self-administration, and *indirect administration*, including the act of prescribing a drug. For example, as used herein, a physician who instructs a patient to self-administer a drug and/or provides a patient with a prescription for a drug is administering the drug to the patient.
- 5 [0019] As used herein, a “manifestation” of BPH refers to a symptom, sign, anatomical state (e.g., prostate size), physiological state (e.g., PSA level), or report (e.g., AUASI score) characteristic of a subject with BPH.
- [0020] As used herein, a “therapeutically effective amount” of a drug is an amount of a drug that, when administered to a subject with BPH, will have the intended therapeutic effect, e.g., alleviation, amelioration, palliation or elimination of one or more manifestations of BPH in the subject. The full therapeutic effect does not necessarily occur by administration of one dose, and may occur only after administration of a series of doses. Thus, a therapeutically effective amount may be administered in one or more administrations.
- 10 [0021] As used herein, a “prophylactically effective amount” of a drug is an amount of a drug that, when administered to a subject, will have the intended prophylactic effect, e.g., preventing or delaying the onset (or reoccurrence) of disease or symptoms, or reducing the likelihood of the onset (or reoccurrence) of disease or symptoms. The full prophylactic effect does not necessarily occur by administration of one dose, and may occur only after administration of a series of doses. Thus, a prophylactically effective amount may be administered in one or more administrations.
- 15 [0022] As used herein, “TID” and “QD” have their ordinary meanings of “three times a day” and “once daily,” respectively.
- [0023] As used herein, “alkyl” refers to a monovalent alkane (hydrocarbon) derived radical containing from 1 to 15 carbon atoms. It may be straight, branched or cyclic and may be unsubstituted or substituted with substituent groups including but not
- 20
- 25
- 30

limited to hydroxyl, halide, alkoxy, and nitrile. Alkoxy groups that can be used include but are not limited to methoxy. Illustrative straight or branched alkyl groups include methyl, ethyl, propyl, isopropyl, butyl and t-butyl.

[0024] As used herein, "aryl" refers to moieties that include one or more monocyclic or fused ring aromatic systems. Such moieties include any moiety that includes one or more monocyclic or bicyclic fused ring aromatic systems, including but not limited to phenyl and naphthyl. Aryl groups may be unsubstituted or substituted with substituent groups as listed for the particular substituted aryl.

[0025] As used herein, "heteroaryl" refers to monocyclic aromatic groups having 5 or 6 ring atoms, or fused ring bicyclic aromatic groups having 8 to 10 atoms, in which the ring atoms are C, O, S, SO, SO₂, or N and at least one of the ring atoms is a heteroatom, i.e., O, S, SO, SO₂, or N. Heteroaryl groups may be unsubstituted or substituted with substituent groups as listed for the particular substituted heteroaryl.

Examples of monocyclic aromatic heteroaryl groups include but are not limited to pyridyl. Examples of bicyclic fused ring heteroaryl groups include but are not limited to indazolyl, pyrrolopyrimidinyl, indolizinyl, pyrazolopyridinyl, triazolopyridinyl, pyrazolopyrimidinyl, triazolopyrimidinyl, pyrrolotriazinyl, pyrazolotriazinyl, triazolotriazinyl, pyrazolotetrazinyl, hexaaza-indenyl, and heptaaza-indenyl. Unless indicated otherwise, the arrangement of the hetero atoms within the ring may be any arrangement allowed by the bonding characteristics of the constituent ring atoms.

[0026] As used herein, the terms "heterocycloalkyl" and "heterocyclyl" refer to a monocyclic or fused ring multicyclic cycloalkyl group at least a portion of which is not aromatic and in which one or more of the carbon atoms in the ring system is replaced by a heteroatom selected from O, S, SO, SO₂, or N. Examples of heterocyclyl groups include but are not limited to piperidinyl, morpholinyl, pyrrolidinyl, tetrahydrofuranyl, tetrahydroimidazo [4,5-c] pyridinyl, imidazolinyl, piperazinyl, pyrrolidine-2-onyl, and piperidin-2-onyl.

[0027] As used herein, "cycloalkyl" refer to a monocyclic or fused ring multicyclic group at least a portion of which is not aromatic and in which the ring atoms are carbon.

[0028] As used herein "heterocycloalkenyl" refers to a monocyclic or fused ring multicyclic group in which one or more of the carbon ring atoms is replaced by a hetero

atom, the ring system is at least partially not aromatic, and the ring system includes at least one carbon-carbon double bond.

2. Benign Prostatic Hyperplasia and the Effects of Lonidamine and Lonidamine Analogs

[0029] The present invention provides compositions and methods useful in the treatment of benign prostatic hyperplasia (BPH). In particular, the invention relates to the use of lonidamine (LND) for the treatment or prevention of BPH. Additionally, the invention relates to the use of lonidamine analogs for the treatment or prevention of BPH. To aid in understanding the invention, a brief discussion of BPH (also referred to as benign prostatic hyperplasia) and the properties of lonidamine and its bioactive analogs is provided below.

[0030] BPH involves overgrowth (hyperplasia) of cells in the prostate, resulting in enlargement of the prostate and leading to lower urinary tract symptoms and disease. The prostate gland contains secretory epithelial cells in a stroma of connective tissue and smooth muscle (see Barry, 2003, for a more detailed description of prostate anatomy), and BPH involves hyperplasia of the epithelial component. The secretory epithelial component in the normal prostate is remarkable in that the level of zinc in this tissue is very high compared to other normal tissues. A consequence of the high zinc levels is that, through a mechanism involving zinc inhibition of the enzyme m-aconitase, the generation of energy via the tricarboxylic acid (TCA) cycle and oxidative phosphorylation is substantially reduced in the secretory epithelium, making this tissue far more dependent than other organs and tissues upon glycolysis as an energy source. The zinc inhibition of m-aconitase, a key enzyme in the TCA cycle, results in at least a substantial reduction in, and perhaps a near complete blockade of, the TCA cycle in prostate epithelial cells. Another physiological result of the zinc-based inhibition of m-aconitase is the diversion of citrate from the TCA cycle, enabling the prostate to secrete large quantities of citrate, used by the sperm as an energy source, into the seminal fluid. See, generally, Costello, 1999; Costello *et al.*, 2000; Costello and Franklin, 2000.

[0031] As other normal cells in the body do not accumulate zinc to a level inhibitory to the metabolism of citrate, prostate epithelial cells are uniquely dependent on glycolysis (anaerobic metabolism). The present invention relates in part to the discovery of these cells' susceptibility to the drug lonidamine, which allows lonidamine

to be administered, as described herein, to treat or prevent BPH in humans.

Lonidamine is the generic name for 1-(2,4-dichlorobenzyl)-1H-indazole-3-carboxylic acid, and has also been referred to in the medical literature as 1-[(2,4-

dichlorophenyl)methyl]-1H-indazole-3-carboxylic acid, AF1890, diclondazolic acid

5 (DICA), and DoridaminaTM. See Figure 1. Lonidamine was first identified as an antispermatogenic agent, and subsequently used in the treatment of breast, cervical, lung and prostate cancers, in a few countries in Europe. See Silvestrini, 1981; Gatto *et al.*, 2002. The mechanisms of action of Lonidamine in spermatogenesis and cancer may not be completely understood. However, it has been suggested that Lonidamine's 10 anticancer properties result at least in part from a Lonidamine-mediated disruption of the mitochondrial membrane, resulting in reduced activity of mitochondrially-bound hexokinase and interference with ATP production by the glycolytic pathway and oxidative phosphorylation. See, Floridi *et al.*, 1981, Fanciulli *et al.*, 1996, and references numbered 15-22 therein; and Gatto, 2002. Also see Kaplan, 2000. Without 15 intending to be bound by a specific mechanism for the effects of Lonidamine in benign prostatic hyperplasia, it is believed that Lonidamine inhibits glycolysis and/or impairs the already diminished mitochondrial function in prostate epithelial cells, starving these cells, relative to the normal cells in the body, of energy. Without intending to be bound by a specific mechanism, it is believed that, due to this energy deprivation, enough of 20 the hyperplastic, epithelial cells are destroyed or otherwise reduced in size to reduce the size of the prostate and thereby relieve the condition and its clinical consequences.

[0032] Accordingly, administration of Lonidamine to a human subject diagnosed with, or exhibiting symptoms of, BPH provides benefits such as reduction of severity or frequency of one or more symptoms, reduction in prostate size or rate of enlargement,

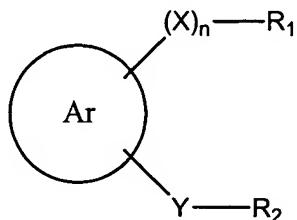

25 improvement in perceived quality of life, and reversion of other manifestations of BPH toward a more normal state. Further, administration of Lonidamine to a human subject in need of prophylaxis for BPH provides benefits such as a reduction in likelihood that BPH will appear, reappear or progress in the subject. Still further, administration of a Lonidamine analog to a human subject is similarly effective for treatment and prophylaxis 30 of BPH. In another embodiment, administration of Lonidamine or its analogs to a human subject as described herein can be efficacious in the treatment of acute urinary

retention. These and other aspects of the invention are discussed in greater detail below. Section 3, below, describes certain Ionidamine analogs useful for treatment and prophylaxis of BPH. Section 4 relates to synthesis and forms of Ionidamine and Ionidamine analogs. Section 5 describes patient populations for whom administration of
5 Ionidamine and Ionidamine analogs provides benefit. Section 6 describes methods of administration of Ionidamine (e.g., dose, route, schedule and duration of administration). Section 7 describes combination therapies in which Ionidamine or an analog is administered in combination with another drug or therapy. Section 8 describes exemplary dosage forms. Section 9 provides examples of the use and effects of
10 Ionidamine. The description below is organized into sections for convenience only, and disclosure found in any organizational section is applicable to any aspect of the invention.

3. Ionidamine Analogs

[0033] As noted above, in addition to Ionidamine, a variety of compounds related to Ionidamine are useful for the treatment and prevention of BPH. Useful compounds are generally structurally similar to, are bioisosteres of, or are pharmacophores of Ionidamine, as described below, and have biological activity(s) similar to those of Ionidamine, as also discussed below. Such compounds can be referred as "bioactive Ionidamine analogs," "Ionidamine analogs," or, in some cases, simply, "analogs."
20 [0034] Structural characteristics of Ionidamine analogs. Based, in part, on the structure of Ionidamine and related compounds known to have pharmaceutical activities similar to that of Ionidamine, certain Ionidamine analogs, including novel analogs provided by the present invention, suitable for use in treatment or prophalaxis of BPH are described by the formula,

25

where R₁, R₂, X, Y, n and \textcircled{Ar} are defined below:

[0035] R₁ represents -COOH or a derivative or bioisostere of the -COOH group.

R₁ is usually selected from an acid group of formula -COOH; an amide of formula -

CONR₃R₄, where R₃ and R₄ may be independently alkyl or hydrogen, with hydrogen

5 preferred; a hydrazide of formula -CONHNR₆R₇, where R₆ and R₇ are usually -H or -

CH₃; a substituted ester of formula -COOR₅, with R₅ being a residue easily hydrolyzed

in the subject after administration and generally a straight chain or branched chain alkyl

group substituted with one or more hydroxyl groups, more usually a straight chain or

branched chain methyl, ethyl, or propyl group substituted with one or more hydroxyl

10 groups, more usually still an ethyl group substituted with one hydroxyl group or a

straight chain or branched chain propyl group substituted with two hydroxyl groups, and

most usually -CH₂CH₂OH, -CH₂CH(OH)CH₂OH, or -CH₂(CH₂OH)₂. R₁ may also be the

carboxylate anion of formula -COO⁻, in which case the Ionidamine or Ionidamine analog

will be associated with a counter ion, Z⁺, where Z⁺ is a pharmaceutically acceptable

15 cation.

[0036] R₂ represents a substituted or unsubstituted aryl or heteroaryl group.

Usually, R₂ is a substituted aryl group; more usually, a substituted phenyl group; more

usually still, a phenyl group substituted by one, two, or three substituents independently

selected from halo and alkyl substituents, particularly -Cl, -Br, -I, CF₃ and -CH₃

20 substituents. When R₂ is a substituted phenyl group, R₂ is usually -Cl, -Br, -I, CF₃ or -

CH₃, monosubstituted phenyl, substituted at the 2, 3, or 4 position; dichloro, dibromo,

dimethyl, or chloro and methyl disubstituted phenyl, substituted at the 2 and 3 or 2 and

4 positions; or 2, 4, 5 trichlophenyl. When R₂ is a substituted phenyl group, R₂ is more

usually 2,4-dichlorophenyl or 4-chloro-2-methylphenyl.

25 [0037] X represents a straight chain or branched chain, saturated or unsaturated

hydrocarbon linkage group. When X is a saturated hydrocarbon linkage group, X is

usually a straight chain linkage group and usually X has the formula -(CH₂)_p-, with p

equal to 1, 2, or 3. When X is a saturated hydrocarbon linkage group, X is most usually

a methylene group, -(CH₂)-. When X is an unsaturated hydrocarbon linkage group, X is

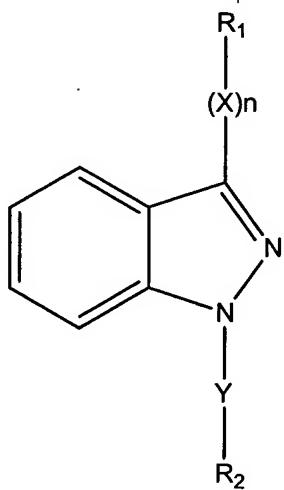

30 usually a straight chain linkage group, most usually -(CH=CH)-.

[0038] Y represents a moiety of formula -CHR₇-, where R₇ is hydrogen or a straight chain or branched chain alkyl group, more usually R₇ is hydrogen or or a straight chain alkyl group, more usually still R₇ is hydrogen, methyl, ethyl, or n-propyl, more usually still R₇ is hydrogen or methyl, and most usually R₇ is hydrogen (i.e., Y is most usually -CH₂-).

5 [0039] n is zero or, most usually, one.

[0040] ^{Ar} is a core ring system that may generally be an aryl, heteroaryl, cycloalkyl or heterocyclyl ring system. The Ar core ring system usually includes 2 fused rings. The fused rings may generally be 4-, 5-, 6-, 7-, or 8-membered rings, more 10 usually 5- or 6-membered rings. The core ring system is most usually fused 5- and 6-membered rings. The fused ring atoms may generally be any atom, usually carbon or hetero atoms, more usually carbon and nitrogen group atoms, and more usually still carbon and nitrogen. The number of carbon atoms in the core ring system is usually 7. The core ring system usually contains 2 hetero atoms, where the preferred hetero atom 15 is nitrogen. Generally, one or more of the fused rings may be aromatic. When the core ring system is fused 5- and 6- membered rings, the core ring system is usually aromatic over both fused rings. The fused 5- and 6-membered ring system is most usually an indazole.

[0041] More particularly, Ionidamine analogs for use according to the methods of 20 the invention, and certain of the novel analogs provided by the invention, include analogs of the formula

where R₁, R₂, X, Y, and n are generally as above or, in a preferred version,

R₂ is -Cl, -Br, -I, or -CH₃, monosubstituted phenyl, substituted at the 2, 3, or 4 position; dichloro, dibromo, dimethyl, or chloro and methyl disubstituted phenyl,

5 substituted at the 2 and 3 or 2 and 4 positions; or 2, 4, 5 trichlophenyl;

Y is -(CH₂)-; and

n is zero, and R₁ is -COOH, -CONH₂, -CONHNH₂, -CONHN(CH₃)₂, -CH₂CH₂OH, -CH₂CH(OH)CH₂OH, or CH₂(CH₂OH)₂; or

n is one, R₁ is -COOH, and X is -CH=CH-.

10 [0042] In one embodiment, the Ionidamine analog is a 1,3-substituted-indazole, such as a 1-halobenzyl-1H-indazole. In another embodiment, the Ionidamine analog is a 3-substituted 1-benzyl-1H-indazole. In another embodiment, the Ionidamine analog is a 1-substituted-indazole-3-carboxylic acid, such as a 1-halobenzyl-1H-indazole-3-carboxylic acid.

15 [0043] Bioisosteres. In addition, Ionidamine analogs that may be used in the treatment methods of the invention include bioisosteres and pharmacophores of Ionidamine and analogs described herein. Bioisosterism is a well-known tool for predicting the biological activity of compounds, based upon the premise that compounds with similar size, shape, and electron density can have similar biological activity. To form a bioisostere of a given molecule, one replaces one or more atoms or groups with known bioisosteric replacements for that atom or group. Known bioisosteric replacements include, for example, the interchangeability of -F, -OH, -NH₂, -Cl, and -CH₃; the interchangeability of -Br and -i-C₃H₇; the interchangeability of -I and -t-C₄H₉; the interchangeability of -O-, -S-, -NH-, -CH₂, and -Se-; the interchangeability of -N=, -CH=, and -P= (in cyclic or noncyclic moieties); the interchangeability of phenyl and pyridyl groups; the interchangeability of -C=C- and -S- (for example, benzene and thiophene); the interchangeability of an aromatic nitrogen (R₁-N(R₃)-R₂) for an unsaturated carbon (R₁-C(=R₃)-R₂); and the interchangeability of -CO-, -SO-, and -SO₂. These examples are not limiting on the range of bioisosteric equivalents and one of skill in the art will be able to identify other bioisosteric replacements known in the art. See, e.g., Patani and LaVoie, 1996; and Burger, 1991.

[0044] Pharmacophores. In addition to the lonidamine analogs described herein, lonidamine analogs that may be used in the methods of the invention can generally be any pharmacophore of lonidamine and the lonidamine analogs described above. Often a reasonable quantitative prediction of the binding ability of a known molecule can be

5 made based on the spatial arrangement of a small number of atoms or functional groups in the molecule. Such an arrangement is called a pharmacophore, and once the pharmacophore or pharmacophores in a molecule have been identified, this information can be used to identify other molecules containing the same or similar pharmacophores. Such methods are well known to persons of ordinary skill in the art of medicinal

10 chemistry, and as the structural information described in this application identifies the pharmacophore of lonidamine and the lonidamine analogs relevant to treatment of BPH, those of skill in the art can identify other LND analogs that comprise the pharmacophore and so are useful in treating BPH. An example of programs available to perform pharmacophore –related searches is the program 3D Pharmacophore search from the

15 Chemical Computing Group (see <http://www.chemcomp.com/fdept/prodinfo.htm>).

[0045] A lonidamine analog of particular interest is tolnidamine (1-(4-chloro-2-methylbenzyl)-1H-indazole-3-carboxylic acid, AF 1923); see Ansari *et al.*, 1998; Corsi *et al.*, 1976. Tolnidamine (TND) differs from lonidamine by the presence of a methyl substituent, rather than a chlorine substituent, in position 2 of the benzyl group. Other

20 analogs of lonidamine with biological activity have been described in the following publications: U.S. Patent No. 3,895,026 entitled "Substituted 1-Benzyl-1H-Indazole-3-Carboxylic Acids and Derivatives Thereof;" Corsi *et al.*, 1976, "1-Halobenzyl-1H-Indazole-3-Carboxylic Acids. A New Class of Antispermatogenic Agents," *Journal of Medicinal Chemistry* 19:778-83; Silvestrini, 1981, "Basic and Applied Research n the

25 Study of Indazole Carboxylic Acids," *Cancer Therapy* 27:9-20; Lobl *et al.*, 1981, "Effects of Lonidamine (AF 1890) and its analogues on follicle-stimulating hormone, luteinizing hormone, testosterone and rat androgen binding protein concentrations in the rat and rhesus monkey," *Cancer Therapy* 27:61-76; U.S. Patent 6,001,865 entitled "3-Substituted 1-Benzyl-1H-Indazole Derivatives As Antifertility Agents"; and Cheng *et al.*, 2001, "Two

30 new male contraceptives exert their effects by depleting germ cells prematurely from the

testis," *Biol Reprod.* 65:449-61, which describe AF-2364 and AF-2785 and other compounds (see Figure 1).

[0046] Functional characteristics of Ionidamine analogs. Ionidamine analogs suited for use in the invention are those that interfere with cellular energy metabolism of prostate epithelial cells when administered to a human, non-human primate, or other mammal. As is usual in the pharmaceutical arts, not every structural analog of a compound (e.g., Ionidamine) is pharmacologically active. Active forms can be identified by routine screening of analogs for the activity of the parent compound. A variety of assays and tests can be used to assess pharmacological activity of Ionidamine analogs, including *in vitro* assays, such as those described below and elsewhere herein, *in vivo* assays of prostate function (including citrate production and ATP production) in humans, non-human primates and other mammals, *in vivo* assays of prostate size in humans, non-human primates and other mammals, and/or clinical studies.

[0047] Apoptosis assay in cell lines. As shown in Example 3, Ionidamine induces apoptosis in cell lines derived from human prostate cells. The induction of apoptosis is significantly greater in LNCaP cells (ATCC NO. CLR-1740), a prostate-derived cell line that is citrate-producing, than in PC3 cells (ATCC NO. CLR-1435), a prostate-derived cell line that is citrate-oxidizing, consistent with the susceptibility of the citrate-producing prostate cells to metabolic inhibitors such as Ionidamine. In some embodiments of the invention in which a Ionidamine analog is used for treatment or prevention of BPH or its manifestations, an analog with similar apoptosis-inducing activity is selected. Thus, in some embodiments of the invention, a Ionidamine analog that induces apoptosis (enhances caspase 3 activity) in citrate-producing prostate cells, such as LNCaP cells, is administered to treat BPH. In some embodiments of the invention, a Ionidamine analog that induces apoptosis in LNCaP cells to a significantly greater degree than in PC3 cells is administered to treat BPH. In some embodiments of the invention, the induction of apoptosis by the Ionidamine analog is at least about 2-fold greater in LNCaP cells than in PC3 cells (and sometimes at least about 3-fold greater, at least about 4-fold greater, or at least about 10-fold greater) when assayed at the concentration of analog at which the difference in the level of apoptosis in the two cell

lines is greatest (provided that the concentration of analog used in the assay is not greater than 1 mM).

[0048] Apoptosis assay in primary cell cultures. As shown in Example 3, Ionidamine induces apoptosis in primary cultures of human prostate epithelial cells. The induction of apoptosis is significantly greater in primary cultures of prostate epithelial cells than in primary cultures of human prostate stromal cells, consistent with the susceptibility of citrate-producing prostate cells to metabolic inhibitors such as Ionidamine. In some embodiments of the invention in which a Ionidamine analog is administered for treatment or prevention of BPH or its manifestations, an analog with apoptosis-inducing activity similar to that of Ionidamine is selected. Thus, in some embodiments of the invention, a Ionidamine analog that induces apoptosis in prostate epithelial cells is administered to treat BPH. In some embodiments of the invention, a Ionidamine analog that induces apoptosis in primary cultures of prostate epithelial cells to a significantly greater degree than in primary cultures of human prostate stromal cells is used. In some embodiments of the invention, the Ionidamine analog does not significantly induce apoptosis in stromal cells. In some embodiments of the invention, induction of apoptosis by the Ionidamine analog is at least 2-fold greater in epithelial cells than in stromal cells (and sometimes at least 4-fold greater, sometimes at 10-fold greater, and sometimes at least 20-fold greater) when assayed at the concentration of analog at which the difference in the level of apoptosis in the two cell lines is greatest (provided that the concentration of analog used in the assay is not greater than 1 mM).

[0049] HIF-1 α expression assays. As shown in Example 2, Ionidamine reduced HIF-1 α expression/accumulation (measured in the nuclear fraction) in cells cultured under conditions of hypoxia by almost 2-fold at 200 micromolar and by more than 5 fold (i.e., more than 10-fold) at higher Ionidamine concentrations. Thus, in some embodiments of the invention, an energolytic agent reduces HIF-1 α expression (prevents HIF-1 α accumulation) in LNCaP cells cultured under hypoxic conditions by at least about 2-fold, at least about 5-fold or at least about 10-fold compared to culture in the absence of Ionidamine.

[0050] In the figures corresponding to Example 2, the effect of Ionidamine on HIF-1 α expression in prostate cells appears more pronounced in LNCaP cells than in

PC3 cells cultured under hypoxic conditions (oxygen level <0.1%). Some lonidamine analogs useful for treatment of BPH according to the present invention may have a similar effect.

[0051] The results of these experiments do not definitively establish the mechanism or specificity of inhibition of HIF-1 α by lonidamine. Lonidamine's effect on HIF-1 α levels may be due entirely or in part to a general inhibition of protein synthesis, described as an activity of lonidamine by Floridi et al., 1985. Lonidamine's effect on HIF-1 α levels could also be due entirely or in part to lonidamine's effect on oxygen utilization by mitochondria. Hagen et al., 2003, reported that HIF-1 α is constitutively synthesized but degraded in the presence of oxygen. It is possible that, under hypoxic conditions, inhibition of mitochondrial respiration by lonidamine reduces oxygen consumption by mitochondria. This in turn could lead to enhanced activity of the oxygen-dependent enzyme, prolyl hydrolase, which plays a role in the HIF-1 α degradation pathway.

[0052] Hexokinase activity. As discussed above, and without intending to be bound to any specific mechanism, the effects of lonidamine on the prostate may be mediated, at least in part, by its effects on mitochondria and mitochondrial hexokinase activity in secretory epithelial cells. Accordingly, some lonidamine analogs useful in the present invention have hexokinase inhibitory activity as great or greater than that of lonidamine. Assays for hexokinase activity are known in the art. See Fanciulli et al., 1996, and Floridi et al., 1981.

[0053] Antispermatogenic activity. Likewise, it is believed that the antispermatogenic activity of lonidamine results, at least in part, from energolytic effects in germ cells. Some lonidamine analogs useful in the present invention have antispermatogenic activity as great, or greater, than that of lonidamine. Assays for antispermatogenic activity are known in the art. See, e.g., Grima et al., 2001; Lohiya et al., 1991.

[0054] In addition to *in vitro* assays, energolytic agents can be evaluated *in vivo* for use in the methods of the invention. For example and without limitation, suitable assays include measurements of prostate function and activity.

[0055] In vivo measurements of prostate function. The effect of a compound on prostate function, and, in particular, on respiration, can be assessed by monitoring

prostate tissue metabolism following administration of the compound. Some Ionidamine analogs useful in the present invention will detectably reduce ATP, citrate, and/or lactate production by the prostate in animals (including humans, non-human primates and other mammals). ATP, citrate, and/or lactate levels can be monitored directly 5 and/or indirectly *in vivo* using techniques of magnetic resonance spectroscopy (MRS) or other methods. See, for example, Narayan and Kurhanewicz, 1992; Kurhanewicz *et al.*, 1991; Thomas *et al.*, 1990, for MRS assays that can be applied for this purpose.

[0056] *In vivo* measurements of prostate size. The effect of a compound on prostate size can be assessed following administration of the compound using standard 10 methods (for example, ultrasonography or digital rectal examination, for humans, and ultrasonography and/or comparison of organ weight in animals). Assays can be conducted in humans or, more usually, in healthy non-human animals or in monkey, dog, rat, or other animal models of BPH (see, Jeyaraj *et al.*, 2000; Lee *et al.*, 1998; Mariotti *et al.*, 1982). Some Ionidamine analogs useful in the present invention will 15 detectably reduce prostate size in such assays and animal models.

[0057] Clinical trials. Clinical trials, such as that described for Ionidamine in the Example, *infra*, can be used to assess the therapeutic effects of Ionidamine analogs.

[0058] The activity of a Ionidamine analog of interest in any of the aforementioned assays can be compared with that of Ionidamine to provide guidance 20 concerning dosage schedules for the compound, and other information. Generally, Ionidamine analogs with greater biological activity per mg than Ionidamine are of special interest.

4. Synthesis and Forms of Lonidamine and Lonidamine Analogs

[0059] Lonidamine and Lonidamine analogs and derivatives can be prepared 25 using by well known synthetic methods. Synthesis of Lonidamine is described in U.S. Patent No. 3,895,026 and Germany Patent No. 2,310,031. Synthesis of exemplary Lonidamine analogs, including tolnidamine (TND), is described in the art (see, e.g., Corsi *et al.*, 1976, "1-Halobenzyl-1H-Indazole-3-Carboxylic Acids. A New Class of 30 Antispermatogenic Agents", *Journal of Medicinal Chemistry* 19:778-83; Cheng *et al.*, 2001, "Two new male contraceptives exert their effects by depleting germ cells

prematurely from the testis" *Biol Reprod.* 65:449-61; Silvestrini, 1981, "Basic and Applied Research in the Study of Indazole Carboxylic Acids" *Cancer Chemotherapy* 27:9-20; Lobl *et al.*, 1981, "Effects of Lonidamine (AF 1890) and its analogues on follicle-stimulating hormone, luteinizing hormone, testosterone and rat androgen binding protein concentrations in the rat and rhesus monkey" *Cancer Chemotherapy* 27:61-76; U.S. Patent Nos. 3,895,026 and 6,001,865).). It will be appreciated, of course, that Ionidamine analogs useful in the practice of the invention are not limited to those for which specific structures are provided in this disclosure or the cited references, and that the compounds described above are provided for illustration and not to limit the present invention. It also will be clear that Ionidamine analogs useful in the methods of the present invention are not limited to those now described herein or elsewhere in the pharmaceutical and patent literature; the ordinarily skilled practitioner guided by the present disclosure can synthesize novel analogs suitable for use according to the present invention using routine methods of medicinal chemistry.

[0060] In certain embodiments, Ionidamine or a Ionidamine analog is provided in the form of a pharmaceutically acceptable salt. Pharmaceutically acceptable salts include addition salts with acids, as well as the salts with bases. Salts with bases are, for example, alkali metal or alkaline earth metal salts, such as sodium, potassium, calcium or magnesium salts, or ammonium salts, such as those with ammonia or suitable organic amines, e.g. diethylamine, di-(2-hydroxyethyl)-amine or tri-(2-hydroxyethyl)-amine. Suitable acids for the formation of acid addition salts are, for example, mineral acids, such as hydrochloric, hydrobromic, sulphuric or phosphoric acid, or organic acids, such as organic sulphonic acids, for example, benzenesulphonic, 4-toluenesulphonic or methanesulphonic acid, and organic carboxylic acids, such as acetic, lactic, palmitic, stearic, malic, maleic, fumaric, tartaric, ascorbic or citric acid.

[0061] Administration of ester, amide and prodrug derivatives of Ionidamine and analogs is also contemplated in the practice of the present invention (see, e.g., U.S. Pat. No. 6,146,658, for general information regarding preparation of such derivatives from a compound of interest) as is administration of polymorphic forms, enantiomeric forms, tautomeric forms, solvates, hydrates, and the like.

5. Patients For Whom Administration of Lonidamine Provides Benefit

[0062] The present invention provides that administration of lonidamine to men afflicted with, or susceptible to, BPH can be therapeutically effective. Accordingly, in one aspect of the invention, lonidamine or a lonidamine analog is administered to a subject in need of treatment for BPH. In one embodiment, the subject in need of treatment is a human male who does not have cancer. As used herein, "a subject in need of treatment for BPH" is a man diagnosed with BPH. BPH is diagnosed using art-known methods and criteria. The most common test is the digital rectal examination in which a physician determines whether the prostate is of a normal size and firmness.

5 Other diagnostic assays include a urine flow rate test, determination of post void residual urine volume (e.g., by palpitation of the abdomen, drainage of residual urine, x-ray urogramraphy, or ultrasonography), moderate or severe symptom scores on the American Urologic Association Symptom Index (AUASI; Barry *et al.*, 1992) or International Prostate Symptom Score (IPSS; Barry *et al.*, 2001), and other tests known 10 in the art.

[0063] Desired clinical results of treatment for BPH include, but are not limited to, alleviation or amelioration of one or more symptoms of BPH (see below), a reduction in prostate size (see below), a reduction in AUASI or IPSS scores compared to base line measurements prior to commencement of therapy (for example, by 3 points or more, 15 such as by 5 points or more), AUASI or IPSS scores less than 8, a reduction in serum PSA by at least about 20%, such as by at least about 40%, a serum PSA less than 4, such as less than 2, improvement in urodynamic parameters, and other desired results 20 that will be recognized by a treating physician as indicative of a reduction in severity of BPH in a subject. An assessment of the response to treatment can be made at any time following the first administration of the drug. For example, an assessment is made 25 about 30 days, about 60 days, or about 90 days after beginning treatment.

Alternatively, assessment can be made about 6, 12, 18, 24 or more months after beginning treatment. Alternatively, an assessment can be made less than about 30 days, about 30 days, about 60 days, or about 90 days after a course of treatment ends.

30 [0064] In a related aspect, lonidamine or a lonidamine analog is administered to a human subject exhibiting a symptom associated with BPH to reduce the frequency or

severity of the symptom. As used herein, "a symptom associated with BPH" refers to any one or more of the following symptoms: (1) urinary urgency; (2) terminal dribbling of urine; (3) frequent urination; (4) nocturia; (5) a weak/slow stream of urine; (6) a sense of incomplete emptying; (7) intermittency; (8) straining; (9) dysuria; (10) hematuria; (11) 5 acute urinary retention; (12) urinary tract infection; (13) incontinence. Administration of Ionidamine or a Ionidamine analog according to the methods of the invention typically results in a reduction in severity, or elimination, of one or more of these symptoms; usually results in either a reduction in severity of, or elimination of, all of these symptoms; and often results in elimination of all of these symptoms.

10 [0065] In another related aspect, Ionidamine or a Ionidamine analog is administered to reduce prostate size in a human subject in need of such reduction. As used herein, "a subject in need of reduction of prostate size" is a man having an enlarged prostate gland as determined by (1) imaging (e.g., ultrasonography, magnetic resonance imaging) or (2) one or more signs or symptoms resulting directly or indirectly 15 from compression of the urethra by the prostate (e.g., including the symptoms of BPH discussed herein). A reduction in serum PSA (prostate specific antigen) is also a useful proxy for reduction of prostate volume. Although varying among individuals, enlarged prostates often exceed 30 grams, 40 grams, or 50 grams in size. The degree of reduction of prostate size will vary from subject to subject due to a number of factors, 20 including the degree of enlargement at the time of onset of therapy, but will typically be a reduction of at least about 10% volume, more often at least about 25%, sometimes at least about 40%, sometimes at least about 50%, and sometimes an even greater than 50% reduction in prostate size is observed. This reduction can be determined by imaging or other methods. Serum PSA can also in some instances serve as a useful 25 proxy for prostate volume.

[0066] In a related aspect, Ionidamine or an analog is administered to a subject with a serum PSA level greater than 2 ng/ml. PSA is secreted only by the epithelial cells of the prostate. For men with BPH, higher PSA levels suggest a relatively higher ratio of epithelial cell proliferation to stromal cell proliferation than in men with lower 30 PSA levels. The present invention provides a number of diagnostic methods suitable for use in determining patients who should respond favorably to treatment with Ionidamine

- or an analog. Thus, Ionidamine treatment can provide a therapeutic benefit to subjects with PSA levels greater than 2 ng/ml. Accordingly, subjects predicted to benefit significantly from treatment in accordance with the invention can be selected in a population of men with BPH by identifying subjects with a serum PSA value greater than
- 5 2 ng/ml. In one embodiment of the invention, the subject has a PSA level greater than about 4 ng/ml. Because higher PSA levels are also, and perhaps more closely, associated with prostate cancer than with BPH, in one embodiment, the subject selected for therapy with Ionidamine or an analog has a PSA level less than about 10 ng/ml.
- 10 [0067] In one aspect of the invention, Ionidamine or a Ionidamine analog is administered to a subject who would benefit from prophylaxis of BPH. In one example, "a subject who would benefit from prophylaxis of BPH" is a man previously treated for BPH by surgery, transurethral microwave thermotherapy, transurethral needle ablation, transurethral electrovaporization, laser therapy, balloon dilatation, prostatic urethral stent, drug therapy, or other therapy and not currently diagnosed with or exhibiting symptoms of BPH. In another example, a subject who would benefit from prophylaxis of BPH is a man at increased risk for developing BPH due to age (e.g., men older than 40, older than 50, older than 60, or older than 70 years of age). In another example, a subject who would benefit from prophylaxis of BPH is a man who is asymptomatic, or
- 15 20 has symptoms sufficiently mild so that no clear diagnosis of BPH can be made, but who has an elevated serum PSA level (e.g., PSA > 2 ng/ml or, in some cases, >4 ng/ml).
- [0068] Thus, in some cases, the subject to whom Ionidamine is administered in accordance with the methods of the invention is a man who has previously been treated for BPH, while in other cases the subject is a man who has not previously been treated
- 25 for BPH. Similarly, it will be clear that any references in this section to administration of Ionidamine apply equally to administration of a biologically active Ionidamine analog.
- [0069] In one embodiment of the invention, the subject in need of treatment or prophylaxis for BPH either is not also under treatment for cancer or does not have cancer. In a related embodiment, the subject in need of treatment or prophylaxis for
- 30 BPH has not been diagnosed as having cancer. In one embodiment, the subject in need of treatment or prophylaxis for BPH does not have cancer. In one embodiment,

the subject in need of treatment has a cancer other than prostate cancer but does not have prostate cancer. As used herein, "cancer" has its ordinary medical meaning and refers to a malignancy (including head, neck, prostate and breast cancers, leukemias and lymphomas), generally characterized by *clonality, autonomy, anaplasia*, and

5 *metastasis* (see Mendelsohn, 1991).

[0070] In one embodiment, the invention provides a method of treating BPH in a patient by administering Ionidamine to the patient. In a related embodiment, the invention provides a method for treating BPH comprising (a) administering Ionidamine to a patient diagnosed with BPH and (b) determining whether one or more manifestations 10 of BPH are reduced in the patient. In one embodiment, the invention provides a method for treating BPH by (a) diagnosing BPH in a patient, (b) administering Ionidamine to the patient and (c) determining whether one or more manifestations of BPH are reduced in said patient. In one embodiment, the invention provides a method of treating BPH in a patient by administering a Ionidamine analog to the patient. In a related embodiment, 15 the invention provides a method for treating BPH comprising (a) administering a Ionidamine analog to a patient diagnosed with BPH and (b) determining whether one or more manifestations of BPH are reduced in the patient. In one embodiment, the invention provides a method for treating BPH by (a) diagnosing BPH in a patient, (b) administering a Ionidamine analog to the patient and (c) determining whether one or 20 more manifestations of BPH are reduced in said patient. In the foregoing embodiments, optionally the subject is not diagnosed with or under treatment for cancer; optionally has a PSA less than or equal to 2 ng/ml, optionally has a PSA greater than 2 ng/ml and less than 10 ng/ml.

[0071] In another aspect, the invention provides a method entailing (a) advertising the use of Ionidamine, or a Ionidamine analog, for treatment of BPH, and (b) selling Ionidamine or a Ionidamine analog to individuals for use for treatment of BPH. In one embodiment, the advertising makes reference to a trademark that identifies an Ionidamine product and the Ionidamine sold in step (b) is identified by the same trademark. It will be appreciated that the individuals to whom Ionidamine is sold include 30 corporate persons (corporations) and the like and "selling BPH to individuals for use for

treatment of BPH" includes selling to, for example, a medical facility for distribution to patients for treatment of BPH.

[0072] In another embodiment, the invention provides a method of treating acute urinary retention in a human by administering Ionidamine or a Ionidamine analog to the 5 human. Because acute urinary retention can be a symptom of BPH, this embodiment of the invention is applicable to any subject who suffers from acute urinary retention but has not been diagnosed as having BPH when Ionidamine or a Ionidamine analog is first administered.

6. Dose, Route, Schedule and Duration of Administration

10 [0073] A variety of routes and dosage schedules are appropriate for administration of Ionidamine and Ionidamine analogs according to the invention.

[0074] A preferred mode of delivery of Ionidamine and Ionidamine analogs to a patient is oral delivery. Preferred dosage forms for oral administration are pills, tablets, capsules, caplets, and the like, especially as formulated for sustained release. Other 15 suitable forms for oral administration include troches, elixirs, suspensions, syrups, wafers, lozenges, and the like. Other modes of administration are also contemplated, including parenteral, inhalation spray, transdermal, rectal, intraprostetic injection (e.g., of Ionidamine-containing microparticles) and other routes. Ionidamine and Ionidamine analogs may be formulated in suitable dosage unit formulations containing conventional 20 non-toxic pharmaceutically acceptable carriers, adjuvants and vehicles appropriate for each route of administration. In one embodiment, the dosage form is the 150 mg unit dosage form marketed in Italy under the tradename Doridamina.

[0075] The dose, schedule and duration of administration of Ionidamine and Ionidamine analogs will depend on a variety of factors, including the age, weight and 25 health of the subject, the severity of BPH symptoms, if any, the subject's medical history, co-treatments, therapeutic goal (e.g., therapy or prophalaxis), the mode of administration of the drug, the formulation used, patient response to the drug, and the like. For illustration rather than limitation, three general categories of dosing for administration of Ionidamine and Ionidamine analogs can be described: high dosing, low 30 dosing, and intermediate dosing. For reference, the standard Ionidamine dose used for

the treatment of the specific types of cancer for which Ionidamine has been approved in a few countries in Europe is 150 mg po TID for about thirty days.

[0076] Low dosing. Low dosing is contemplated for the treatment and prophalaxis of BPH. Exemplary low doses of Ionidamine or a Ionidamine analog 5 include, without limitation, doses in the range of 1-300 mg per day (total daily dosage), more often in the range of 5-300 mg/day, or sometimes in the range of 5-70 mg/day. Other exemplary low dose ranges include 1-25 mg/day, 20-45 mg/day, 40-65 mg/day, 10 40-70 mg/day, 50-100 mg/day, 50-200 mg/day, and 50-300 mg/day. In one embodiment, the low dose is 150 mg administered orally once per day; the Doridamina unit dose form can be used in this embodiment. In another embodiment, the low dose is 75 mg administered orally twice daily, the Doridamina unit dose form can be used in this embodiment by splitting it into two equal parts.

[0077] As noted, the daily dosages recommended herein may be divided for, for example, two-, three- or four-times per day administration. In one embodiment, the 15 drug is formulated for administration once-per day. In one embodiment, the drug is formulated for administration less frequently than once per day. In another embodiment, a modified-release form of the drug is used.

[0078] Administration of low doses of Ionidamine can be daily, every other day, five days on, two days off, and other schedules determined by the administering 20 physician.

[0079] An advantage of low dose schedules of the invention is that this dose may be continued to be administered for weeks to months while limiting or eliminating the unwanted, albeit usually mild, side effects reported for higher doses of Ionidamine (principally myalgia and testicular pain).

[0080] A low dose schedule can be used for therapy or prophalaxis. In one embodiment, a low dose form is used for a maintenance dose after a higher initial, priming or loading dose.

[0081] High dosing. In another embodiment, BPH is treated in accordance with the methods of the invention by administering to a BPH patient a higher dose of 30 Ionidamine or a Ionidamine analog (usually for a shorter period of time than for low doses). Exemplary high doses include, without limitation, total daily doses greater than

0.5 g, such as doses in the range 0.5 – 5 g/day, 0.5 – 3 g/day, 0.5 – 1 g/day and 1-3 g/day, or higher doses. The daily dosages may be divided, for example, for two-, three- or four-time per day administration. In one embodiment, the drug is formulated for administration once-per day, or less frequently than once per day. In one embodiment,
5 a modified-release form of the drug is used. Alternatively, a high dose can be administered on a one-time, once-a-week, once every two weeks, or once-a-month basis (e.g., 0.5 – 5 g/administration) or by other schedules to be determined by the administering physician.

10 [0082] A high dose schedule can be used for therapy or prophalaxis. In one embodiment, a high dose is administered in combination with, or following, a surgical or other non-drug treatment for BPH.

15 [0083] Intermediate dosing. In another embodiment, BPH is treated in accordance with the methods of the invention by administering lonidamine or a lonidamine analog to a BPH patient at a dose intermediate between a high dose and a low dose. Exemplary intermediate doses include, without limitation, doses greater than 300 and less than 500 mg/day, such as doses in the range >300-400 or 400<500 (e.g., 450 mg/day). The daily dosages may be divided, for example, for two-, three- or four-times per day administration. In an embodiment, the drug is formulated for administration once-per day or less frequently than once per day. In one embodiment,
20 a modified-release form of the drug is used. Alternatively, this intermediate dose can be administered on a one-time, once-a-week, once every two weeks, or once-a-month basis (e.g., 300 – 500 mg/administration) or by other schedules to be determined by the administering physician. In one embodiment, the daily dosage is 150 mg of lonidamine or a lonidamine analog taken three times a day.

25 [0084] An intermediate dose schedule may be used for therapy or prophylaxis. In one embodiment, an intermediate dose is administered in combination with, or following, a surgical or other non-drug treatment for BPH.

30 [0085] It will be appreciated that these dosing schedules are for illustration and not limitation, and that a dosing schedule may change during a course of therapy based on, for example, a patient's response to the therapy or the use of a lonidamine analog that has an activity/dose profile significantly different from that of lonidamine.

[0086] Duration. In therapeutic and prophylactic applications, Ionidamine or the Ionidamine analog can be administered a single time or many times over periods as long as several months or years. In one embodiment of the invention, Ionidamine or an analog is administered to a symptomatic (e.g., experiencing difficulty in urination) BPH patient only until the symptoms abate or disappear, and then treatment is stopped unless and until symptoms reappear. When symptoms reappear, administration of Ionidamine or an analog is resumed. In another embodiment, treatment continues after symptoms disappear or are reduced to an acceptable target level, at least for a period of time, such as a week, two weeks, a month or several months. In another embodiment, the drug is administered to an asymptomatic subject to prevent the development or reoccurrence of symptoms (i.e., prophylactically administered).

7. Treatment Combinations

[0087] Lonidamine and Ionidamine analogs can be administered to a BPH patient in combination with other agents or procedures intended to treat BPH, ameliorate symptoms of BPH, potentiate the effects of the Ionidamine or Ionidamine analog, or provide other therapeutic benefit. Administration of an agent "in combination with" includes parallel administration (administration of both the agents to the patient over a period of time, such as administration of Ionidamine and tamsulosin on alternate days for one month), co-administration (in which the agents are administered at approximately the same time, e.g., within about a few minutes to a few hours of one another), and co-formulation (in which the agents are combined or compounded into a single dosage form suitable for oral or parenteral administration). Exemplary agents for administration in combination with Ionidamine or Ionidamine analogs include, but are not limited to, zinc, alpha-blockers, 5-alpha-reductase inhibitors, and plant extracts. Other agents for administration in combination with Ionidamine or Ionidamine analogs include other metabolic inhibitors, including but not limited to other hexokinase inhibitors and other inhibitors of glycolysis, including but not limited to 2-deoxy-D-glucose and an inhibitor, direct or indirect, of HIF-1 α .

[0088] Zinc: As discussed above, high concentrations of zinc in the secretory epithelial cells of the prostate inhibit m-aconitase, increasing the dependence of that tissue on glycolysis for energy production. In accordance with the methods of the

present invention, it may in some patients be beneficial to co-administer zinc (e.g., zinc chloride, zinc gluconate, zinc sulfate, zinc acetate, zinc aspartate, zinc citrate, zinc glycerate, zinc oxide, zinc picolinate, etc.) with a drug composition of the invention, to maximize the efficacy of the treatment. For example and not limitation, 15-300 mg/day 5 zinc can be administered for this purpose, typically 30-50 mg/day are administered.

[0089] Alpha-Adrenergic-Blockers: Alpha-blockers alleviate some symptoms of BPH, without curing the underlying disease. These agents work by relaxing the muscles at the neck of the bladder and in the prostate, reducing the pressure on the urethra. Exemplary alpha-blockers include doxazosin (Cardura), terazosin (Hytrin), 10 tamsulosin (Flomax), alfuzosin (Xatral), and prazosin (Hypovase). In one embodiment of the invention, an alpha blocker is administered in combination with lonidamine or a lonidamine analog to treat BPH. In another embodiment, the alpha-blocker is administered at a lower dosage (amount) or less frequently (e.g., alternate days rather than daily) than the "standard" dosage (the dosage that would be indicated for the 15 subject in the absence of lonidamine administration) in combination with lonidamine or a lonidamine analog.

[0090] 5-Alpha-Reductase Inhibitors: 5-alpha-reductase inhibitors inhibit the conversion of testosterone to dihydrotestosterone 2 (DHT), an androgen that contributes to prostate enlargement. An exemplary 5-alpha-reductase inhibitor is 20 finasteride (Proscar). In one embodiment of the invention, a 5-alpha-reductase inhibitor is administered in combination with lonidamine to treat BPH. In another embodiment, the 5-alpha-reductase inhibitor is administered at a lower dosage (amount) or less frequently (e.g., alternate days rather than daily) than the "standard" dosage (the dosage that would be indicated for the subject in the absence of lonidamine 25 administration) in combination with lonidamine (or an lonidamine analog).

[0091] Glycolytic and Mitochondrial Function Inhibitors: Glycolytic inhibitors, such as 2-deoxy-D-glucose and compounds that inhibit glucose transport, mitochondrial function inhibitors, mitochondrial poisons, and hexokinase inhibitors such as 3-bromopyruvate and its analogs can also be used in combination with lonidamine or a 30 lonidamine analog to treat BPH. Such inhibitors are known in the art, and include those described in PCT patent publications WO 01/82926 published 8 November 2001; U.S.

Patent Nos. 6,670,330; 6,218,435; 5,824,665; 5,652,273; and 5,643,883; U.S. patent application publication Nos. 20030072814; 20020077300; and 20020035071; and U.S. patent application Serial No. 10/_____ (filed 9 January 2004; attorney docket number 54492-2000400) entitled "Treatment Of Cancer With 2-Deoxyglucose." Such inhibitors
5 can be administered in combination with Ionidamine or Ionidamine analogs for therapeutic benefit in the treatment of BPH.

[0092] Plants: Saw Palmetto (*Serenoa repens*) or an extract thereof, or *Pygeum Africanum* or an extract thereof can be administered in combination with Ionidamine or Ionidamine analogs for therapeutic benefit in the treatment of BPH.

10 [0093] Procedures. In addition, Ionidamine or a Ionidamine analog may be administered in combination with, or prior to, procedures for treatment of BPH including surgery (transurethral resection of the prostate; transurethral incision of the prostate; or open prostatectomy), laser therapy, transurethral microwave thermotherapy, balloon dilatation, placement of a prostatic urethral stent, transurethral needle ablation,
15 transurethral electrovaporization of the prostate, or other non-drug therapies.

8. Dosage Forms

[0094] Unit Dosage Forms. The compounds used in the methods of the present invention are formulated in compositions suitable for therapeutic administration. In one embodiment, the methods of the invention are practiced with Ionidamine in the unit dosage form marketed as Dordidamina (by ACRAF) in Italy. New dosage forms of Ionidamine are also provided. For example, the present invention provides a unit dosage pharmaceutical formulation of Ionidamine that is suitable for oral administration (including tablets, capsules, caplets, and pills) and contains, in various embodiments, an amount of Ionidamine in a range bounded by a lower limit of (in mg) 1, 5, 10, and 50
20 and an upper limit of 10, 20, 40, 50, 70 and 100 (where the higher limit is in mg and greater than the lower limit) and is especially convenient for certain low dose schedules. In an other embodiment, the unit dosage form contains an amount of drug in a range bounded by a lower limit of (in mg) 200, 300, 500 or 1000 and an upper limit of 500,
25 1000, 3000 or 5000 (where the higher limit is greater than the lower limit) and is especially convenient for certain high dose schedules. In yet other embodiments, the formulation contains between 100 and 200 mg of compound (e.g., 150 mg), between
30

200 and 5000 mg, between 200 and 1000 mg, or between 500 and 1000 mg of the compound. Lonidamine analogs can be similarly formulated.

[0095] In addition to lonidamine and/or lonidamine analogs, solid unit dosage forms of the invention generally include a pharmaceutically acceptable carrier. As used 5 herein, "pharmaceutically acceptable carrier" refers to a solid or liquid filler, diluent, or encapsulating substance, including for example excipients, fillers, binders, and other components commonly used in pharmaceutical preparations, including, but not limited to, those described below. Methods for formulation of drugs generally are well known in the art, and the descriptions herein are illustrative and not limiting. See, e.g., Ansel et 10 al., 1999; Marshall, 1979.

[0096] Hydrophilic binders suitable for use in the formulations of the invention include copolyvidone (cross-linked polyvinylpyrrolidone), polyvinylpyrrolidone, polyethylene glycol, sucrose, dextrose, corn syrup, polysaccharides (including acacia, guar, and alginates), gelatin, and cellulose derivatives (including HPMC, HPC, and 15 sodium carboxymethylcellulose).

[0097] Water-soluble diluents suitable for use in the formulations of the invention include sugars (lactose, sucrose, and dextrose), polysaccharides (dextrans and maltodextrin), polyols (mannitol, xylitol, and sorbitol), and cyclodextrins. Non-water-soluble diluents suitable for use in the formulations of the invention include calcium 20 phosphate, calcium sulfate, starches, modified starches, and microcrystalline cellulose.

[0098] Surfactants suitable for use in the formulations of the invention include ionic and non-ionic surfactants or wetting agents such as ethoxylated castor oil, polyglycolized glycerides, acetylated monoglycerides, sorbitan fatty acid esters, poloxamers, polyoxyethylene sorbitan fatty acid esters, polyoxyethylene derivatives, 25 nonoglycerides or ethoxylated derivatives thereof, sodium lauryl sulfate, lecithins, alcohols, and phospholipids.

[0099] Disintegrants suitable for use in the formulations of the invention include starches, clays, celluloses, alginates, gums, cross-linked polymers (PVP, sodium carboxymethyl-cellulose), sodium starch glycolate, low-substituted hydroxypropyl 30 cellulose, and soy polysaccharides. Preferred disintegrants include a modified cellulose gum such as cross-linked sodium carboxymethylcellulose.

[00100] Lubricants and glidants suitable for use in the formulations of the invention include talc, magnesium stearate, calcium stearate, stearic acid, colloidal silicon dioxide, magnesium carbonate, magnesium oxide, calcium silicate, microcrystalline cellulose, starches, mineral oil, waxes, glyceryl behenate, polyethylene glycol, sodium benzoate, sodium acetate, sodium chloride, sodium lauryl sulfate, sodium stearyl fumarate, and hydrogenated vegetable oils. Preferred lubricants include magnesium stearate and talc and combinations thereof.

5 [00101] The preferred range of total mass for the tablet or capsule may be from about 40 mg to 2 g, from about 100 mg to 1000 mg, and from about 300 mg to 750 mg.

10 [0100] Sustained Release Forms. In addition, the present invention provides unit dosage forms that are sustained release formulations of lonidamine or a lonidamine analog to allow once a day (or less) oral dosing, a frequency sometimes preferred by patients over multiple day dosing. Such sustained release formulations (including tablets, capsules, caplets and pills) of the invention usually contain between 1 mg and 3 g of the active compound, with various alternative embodiments including those described above for conventional oral unit doses, such as an amount of drug in a range bounded by a lower limit of (in mg) 1, 5, 10, and 50 and an upper limit of 10, 20, 40, 50, 70 and 100 (where the higher limit is greater than the lower limit) and are especially convenient for certain low dose or intermediate dose schedules. In another 15 embodiment, the unit dosage form contains an amount of drug in a range bounded by a lower limit of (in mg) 200, 300, 500, 750 or 1000 and an upper limit of 500, 1000, 2000, 3000 or 5000 (where the higher limit is greater than the lower limit).

20 [0101] In one embodiment, lonidamine or a lonidamine analog in the sustained release formulations (also called "modified" or "controlled" release forms) is released over a period of time greater than 6 hours, e.g., greater than 12 hours, after 25 administration. In one embodiment, the sustained release formulation allows once a day dosing to achieve a pharmacodynamic profile therapeutically equivalent to dosing 150 mg of lonidamine three times a day.

30 [0102] Examples of sustained-release formulations for other drugs that can be modified in accordance with the teachings herein to be useful in the present invention are well known in the art, and are, for example, described in U.S. Pat. Nos. 5,968,551;

- 5,266,331; 4,970,075; 5,549,912; 5,478,577; 5,472,712; 5,356,467; 5,286,493; 6,294,195; 6,143,353; 6,143,322; 6,129,933; 6,103,261; 6,077,533; 5,958,459; and 5,672,360. Sustained-release formulations are also discussed in the scientific literature, e.g., in **ORAL SUSTAINED RELEASE FORMULATIONS: DESIGN AND EVALUATION**, edited by A.
- 5 Yacobi and E. Halperin-Walega, Pergamon Press, 1988, which describes a variety of types of sustained-release dosage forms and drug release mechanisms, for example single unit (e.g., matrix tablets, coated tablets, capsules), multiple unit (e.g., granules, beads, micro-capsules), inert, insoluble matrix, hydrophilic gel matrix (e.g., bioadhesive, erodible, non-erodible), and ion-exchange resin sustained-release dosage forms.
- 10 [0103] In one embodiment, the present invention provides a method of treating BPH, by administering once daily to a patient in need of such treatment a sustained release tablet dosage form comprising a daily therapeutic dose of Lonidamine from about 1 mg to 2 g in a hydrophilic matrix. The matrix can be, for example and without limitation, selected from the group consisting of hydroxypropylmethyl cellulose (by weight percent of about 20-40%), lactose (5-15%), microcrystalline cellulose (4-6%), and silicon dioxide (1-5%) having an average particle size ranging from 1-10 microns, often ranging from 2-5 microns, and most often ranging from about 2-3 microns.
- 15 [0104] Illustrative preferred sustained release formulations of the invention include formulations A and B in the table below.
- | | Formulation
(weight percentage) | A | B |
|----|---|------|------|
| 20 | Lonidamine (milled) | 53.8 | 53.8 |
| | HPMC (Methocel K15M, CR) | 8 | 30 |
| 25 | Methyl cellulose (Methocel, K100L, CR) | 18 | 0 |
| | Anhydrous lactose | 12.2 | 8.2 |
| | Microcrystalline cellulose (Avicel PH101) | 5 | 5 |
| | Silicon dioxide (1-10 micron; Syloid 244) | 3 | 3 |
| | Total Table Weight (in grams) | 1 | 1 |
- 30 [0105] The sustained release formulations of the invention may be in the form of a compressed tablet containing an intimate mixture of Lonidamine and a partially neutralized pH-dependent binder that controls the rate of drug dissolution in aqueous media across the range of pH in the stomach (typically ~ 2) and intestine (typically ~5.5).

[0106] Many materials known in the pharmaceutical art as "enteric" binders and coating agents have the desired pH dissolution properties suitable for use in the sustained formulations of the invention. These include phthalic acid derivatives such as the phthalic acid derivatives of vinyl polymers and copolymers, hydroxyalkylcellulose, alkylcelluloses, cellulose acetates, hydroxyalkylcellulose acetates, cellulose ethers, alkylcellulose acetates, and esters thereof, and polymers and copolymers of lower alkyl acrylic acids and lower alkyl acrylates, and the partial esters thereof.

[0107] Preferred pH-dependent binder materials are methacrylic acid copolymers. Such a copolymer is commercially available from Rohm Pharma as EudragitTM L-100-55 as a powder or L30D-55 as a 30% dispersion in water. Other pH-dependent binder materials which may be used alone or in combination include hydroxypropyl cellulose phthalate, hydroxypropyl methylcellulose phthalate, cellulose acetate phthalate, polyvinylacetate phthalate, polyvinylpyrrolidone phthalate, and the like. One or more pH-dependent binders are present in the sustained release oral dosage forms of the invention in an amount ranging from about 1 to 20 weight percent, or from 5 to 12 weight percent, or about 10%.

[0108] The pH-independent binders or viscosity enhancing agents contained in the sustained release formulations of the invention include substances such as hydroxypropyl methylcellulose, hydroxypropyl cellulose, methylcellulose, polyvinylpyrrolidone, neutral poly(meth)acrylate esters, and the like. The pH-independent binders are in an amount ranging from 1 to 10 weight percent or from 1 to 3 weight percent, or about 2%.

[0109] The sustained release formulations of the invention also contain in some embodiments one or more pharmaceutical excipients intimately mixed with the ranolazine (Lonidamine) and the pH-dependent binder, such as pH-independent binders or film-forming agent, starch, gelatin, sugars, carboxymethylcellulose, and the like, as well as other useful pharmaceutical diluents such as lactose, mannitol, dry starch, microcrystalline cellulose, and the like, and surface active agents such as polyoxyethylene sorbitan esters, sorbitan esters, and the like; and coloring agents and flavoring agents. Lubricants such as talc and magnesium stearate and tabletting aids are also present.

[0110] The sustained release formulations of the invention include any of the commercially available polymers suitable for use in such formulations, including but not limited to cellulose, ethyl cellulose, methyl cellulose, carboxymethyl cellulose, hydroxypropylmethyl cellulose, hydroxypropylmethyl cellulose phthalate, hydroxypropyl 5 cellulose, microcrystalline cellulose, sodium carboxymethyl cellulose, cellulose acetate phthalate, polyvinyl acetate phthalate, polyvinylpyrrolidone, polyethylene oxide, polyethylene glycol, zein, alginate, hypromellose phthalate, methacrylic acid copolymer, Crospovidone, silica aerogel, pregelatinized starch, corn starch, croscarmellose sodium, sodium starch glycolate, candelilla wax, paraffin wax, carnauba wax, montan glycol 10 wax, white wax, Eudragit (polymethacrylic acid esters), Aquacoat (ethyl cellulose, cellulose acetate phthalate), Carbopol (acrylic acid polyalkeny polyether copolymer), and Macrogol (polyethylene glycol).

[0111] The sustained release formulations of the invention include formulations that are diffusion controlled, such as those that employ:

- 15 (a) a reservoir system in which the drug is encapsulated in a polymeric membrane, and water diffuses through the membrane to dissolve the drug, which then diffuses out of device;
- (b) a monolithic (matrix) system in which the drug is suspended in a polymeric matrix and diffuses out through long pathways;
- 20 (c) microencapsulation and coated granule systems in which particles of drug (or particles of drug and polymer) as small as 1 micron are coated in a polymeric membrane, including embodiments in which particles coated with polymers with different release characteristics are delivered together in a capsule;
- (d) solvent-activated systems, including (i) osmotically controlled devices
- 25 (e.g. OROS) in which an osmotic agent and the drug are encapsulated in a semi-permeable membrane, water is pulled into device due to osmotic gradient, and increased pressure drives drug out of device through a laser drilled hole; (ii) a hydrogel swelling system in which drug is dispersed in a polymer and/or a polymer is coated onto a particle of drug, and the polymer swells on contact with water (swelling is in some 30 embodiments pH or enzymatically controlled), allowing diffusion of drug out of the device; (iii) a microporous membrane system in which drug is encapsulated in a

membrane that has a component that dissolves on contact with water (in some embodiments, dissolution is pH or enzymatically controlled), leaving pores in the membrane through which the drug diffuses; and (iv) a wax matrix system in which the drug and an additional soluble component are dispersed in wax, such that, when water

5 dissolves the component, diffusion of drug from the system is allowed; and

(e) polymeric degradation systems, including (i) bulk degradation, in which drug is dispersed in polymeric matrix, and degradation occurs throughout the polymeric structure in a random fashion, allowing drug release; and (ii) surface erosion, in which drug is dispersed in polymeric matrix and delivered as the surface of the polymer

10 erodes.

[0112] In one aspect, the invention provides a method for treating BPH by administering a unit dose oral pharmaceutical composition that is a sustained-release formulation containing an effective amount of lonidamine, such as described above, once per day.

15 9. Examples.

EXAMPLE 1
CLINICAL TRIAL

[0113] A Phase II randomized dose comparison study of lonidamine administration for the treatment of symptomatic benign prostatic hyperplasia is conducted. Patients

20 are males 50 to 80 years of age with BPH confirmed by ultrasonography, a serum PSA >2, and no evidence of prostate cancer. Lonidamine (150 mg tablet; Doridamina formulation) is administered 150 mg p.o. TID (intermediate dosage) or QD (low dosage) 8 weeks. Patients receiving TID dosing take the compound 5 days on and 2 days off to aid compliance with the protocol.

25 [0114] Patients are assessed at baseline, day 30 and day 60 for prostate volume by ultrasonography, urine flow, AUASI score, PSA, adverse events, and serum chemistry to determine whether one of the two doses provides significantly greater benefit than the other dose and to measure the reduction in prostate size achieved by the therapy.

EXAMPLE 2

LONIDAMINE REDUCES EXPRESSION OF HIF-1 α IN PROSTATE CELLS

[0115] This example shows the effects of lonidamine treatment on HIF-1 α expression in two cell lines derived from metastatic lesions of human prostate cancers.

5 LNCaP is a citrate-producing cell (ATTC No. CRL-1740) while PC3 is citrate oxidizing cell (ATTC No.CRL-1435). See Franklin et al; 1995. Cells may be obtained from the American Type Culture Collection (ATCC), P.O.Box 1549, Manassas, VA 20108 USA.

[0116] As shown in Figures 2 and 3, lonidamine treatment reduced the level of HIF-1 α protein detected in nuclear (NE) and whole-cell extract (WCE) preparations. The 10 inhibition was dose-dependent, and observed under normoxic (PC3 cells only) and hypoxic conditions (LNCaP cells and PC3 cells). The lonidamine effect was specific to the HIF-1 α subunit under the conditions tested and, except at 800 μ M concentration, had no detectable inhibition under the conditions tested on the protein levels of actin, caspase 3, NF- κ B, or I κ B α . Lonidamine has, however, been reported to inhibit protein 15 synthesis generally (see Floridi et al., *supra*), and the results presented herein should not be construed as definitive evidence that lonidamine is a specific inhibitor of HIF-1 α or that lonidamine's therapeutic effect in the treatment of BPH is in whole or in part due to its inhibitory effect on the accumulation of HIF-1 α in any cell type.

[0117] Methods: Cells were plated at a density of 5×10^5 cells into a dish, and then 20 maintained in 37°C incubator (5% CO₂) for 2 days. Prior to the assay, cells were rinsed twice with pre-warmed (37°C) RPMI-1640 Medium (ATCC No. 30-2001; 10 mM HEPES; 1 mM sodium pyruvate; 2 mM L-glutamine; 4500 mg glucose/L; 1500 mg sodium bicarbonate/L). Cells were incubated with 2ml culture medium in the absence or presence of lonidamine at different concentrations for 4 hours at 37°C either under 25 normoxia or hypoxia (oxygen level<0.1%). At the end of the incubation, the dish was placed on ice, and the cells were washed rapidly twice with cold PBS buffer (4°C). For nuclear extracts, cells were lysed with buffer A (10 mM Tris, pH7.5; 1.5 mM MgCl₂; 10 mM KCl and protease inhibitors and buffer C (0.5 M NaCl; 20 mM Tris pH7.5; 1.5 mM MgCl₂; 20% glycerol and protease inhibitors), sequentially. The protease inhibitors 30 used in the experiments were a cocktail of five protease inhibitors (500 mM AEBSF-HCl, 1 mg/ml Aprotinin, 1 mM E-64, 500 mM EDTA and 1 mM Leupeptin; Calbiochem NO

539131). For whole cell lysate, cells were lysed with 150 mM NaCl; 10 mM Tris pH7.5; 10 mM EDTA; 1% Triton X-100; 0.5% Deoxycholate, and protease inhibitors. The protein concentration was measured using a Bio-Rad protein assay. Equal amounts of protein were loaded on a SDS-PAGE gel. After transferring of the sample to PVDF
5 membrane, the membrane was blocked with TBST containing 5% non-fat milk overnight at 4°C. Subsequently, the membrane was incubated with primary antibodies (HIF-1 α , HIF-1 β , and actin) and alkaline phosphatase-conjugated secondary antibody, for two hours each incubation. To detect the expression of caspase 3, NF- κ B, P65 and I κ B α , the membrane was blocked with TBST containing 5% non-fat milk for 1 h at room
10 temperature, and the proteins were detected by incubation with the corresponding antibodies overnight at 4°C and with the alkaline phosphatase-conjugated secondary antibody for 1 h. The specific protein was detected using a colorimetric substrate, and the intensity of each protein was quantified using an NIH image system.

[0118] In separate experiments carried out generally as above, the effect of 0 – 600
15 μ M Ionidamine on expression of HIF-1 α and other proteins was determined in LNCaP whole cell extracts (Figure 7) or nuclear extracts (Figure 8) from cells cultured under hypoxic conditions.

EXAMPLE 3

20 LONIDAMINE INDUCES APOPTOSIS IN CITRATE-PRODUCING CELLS

[0119] To determine whether apoptosis occurs in cells treated with Ionidamine, the effect of Ionidamine on cells producing citrate (LNCaP) and cells oxidizing citrate (PC3) was assessed. As shown in Figure 4, Ionidamine induced activation of caspase 3 in
25 citrate-producing cells (LNCaP) to a much greater extent than in citrate-oxidizing cells (PC3). The activation of caspase3 is a time-dependent process (Figure 5).

[0120] The effect of Ionidamine was also examined in primary cultures of prostate epithelial cells (which accumulate citrate) or prostate stromal cells (which do not accumulate citrate). As shown in Figure 6, Ionidamine induced apoptosis only in prostate epithelial cells in a dose-dependent manner. In contrast, induction of apoptosis
30 was not observed in prostate stromal cells after treatment with Ionidamine.

Methods:

[0121] Immunoblotting: Immunoblotting was carried out as described in Example 2.

To detect the expression of caspase 3, the membrane was blocked with TBST containing 5% non-fat milk for 1 h at room temperature, and caspase 3 protein was

5 detected by incubation with caspase 3 antibody for overnight at 4°C and with the alkaline phosphatase-conjugated secondary antibody for 1 h. The specific protein was detected using colorimetric substrate, and the intensity of each protein was quantified using an NIH image system.

[0122] Primary Cell Cultures: Primary cultures of human prostate epithelial cells

10 (Cambrex No. CC-2555) and human prostate stromal cells (Cambrex No. CC-2508) were obtained from Cambrex Bio Science Rockland, Inc. (191 Thomaston Street, Rockland, Maine 04841).

[0123] Apoptosis Assay: Cells were plated at a density of 2×10^4 cells per well in a 96 well plate, and then maintained in a 37°C incubator (5% CO₂) for 16 h. Lonidamine

15 was added into each well at different concentrations, and then incubated for 6 h at 37°C. To assess the caspase 3 activity, the homogeneous buffer and caspase 3 substrate (Promega No G7791; Promega Corporation, 2800 Woods Hollow Road, Madison WI USA 53711) were added into each well in the presence or absence of caspase 3 inhibitor (Promega No G5961). The fluorescence intensity of cleaved

20 substrate was determined using a fluorescence plate reader at excitation 485 nm and emission 530 nm.
